The practice of administering active fluids by drops has been long known to be inaccurate; but the extent of the evil has been only lately ascertained, by the accurate experiments of Mr Shuttleworth, surgeon, of Liverpool. Not only do the drops of different fluids from the same vessel, and of the same

B

fluids from different vessels, differ much in size; but it appears that the drops of the same fluid differ, even to the extent of a third, from different parts of the lip of the same vessel. The custom of dropping active fluids should, therefore, be abolished entirely; and, as weighing is too troublesome and difficult for general use, we must have recourse to small measures, accurately graduated, in the manner of Lane's *drop* measure, and the grain measure recommended by the Edinburgh college; but we must not be misled by their names; for they are measures of bulk, not of drops or of grains.

In the following table, the first column shews the weight, the second the number of drops, and the third the weight of the extract, in a measured drachm of several active fluids, in circumstances as nearly similar as possible, as ascertained by Mr Shuttleworth; the last column shews the number of drops in a drachm of different fluids, according to Dr Niemann.

A tea cup commonly contains three or four ounces of an infusion, decoction, or mixture; a wine glass about an ounce and a half; a table spoon about half an ounce of watery fluids, and two or three drachms of alcoholic; a tea spoon from half a scruple to a scruple of a light powder, such as magnesia, from half a drachm to two scruples of a heavier powder, as sulphur, and from one drachm to four scruples of a metallic oxide; from one scruple to half a drachm of alcoholic fluids, from half a drachm to two scruples of watery fluids; from two scruples to two drachms of tinctures and syrups, and from one to two drachms of electuaries. But all this is very uncertain.
